Pulmonary Fibrosis
FOUNDATION
The mission of the Pulmonary Fibrosis Foundation (PFF) is to serve as the trusted resource for the pulmonary fibrosis (PF) community by raising awareness, providing disease education, and funding research.
PULMONARY FIBROSIS (PF) DESCRIBES A CONDITION in which the lung tissue becomes thickened, stiff, and scarred.¹ The medical terminology used to describe this scar tissue is “fibrosis.” The alveoli (air sacs) and the blood vessels within the lungs are responsible for delivering oxygen to the body, including the brain, heart, and other organs. All of the body’s functions depend upon delivery of a steady supply of oxygen. As lung tissue becomes scarred and thicker, it is more difficult for the lungs to transfer oxygen into the bloodstream. As a result, the brain, heart, and other organs do not get the oxygen they need to function properly.¹ In some cases, doctors can determine the cause of the fibrosis (scarring), but in many cases the cause remains unknown. When there is no known cause for the development of pulmonary fibrosis (and certain radiologic and/or pathologic criteria are met), the disease is called idiopathic pulmonary fibrosis or IPF.² More specifically, consensus treatment guidelines from international lung societies define IPF as “a specific form of chronic, progressive fibrosing interstitial pneumonia of unknown cause, occurring primarily in older adults, limited to the lungs, and associated with the histopathologic and/or radiologic pattern of UIP [usual interstitial pneumonia].”²

There are more than 200 related diseases of the lung known as interstitial lung diseases (ILD), which are also referred to as diffuse parenchymal lung diseases or DPLD. Because these diseases affect the interstitium—the walls of the air sacs of the lung—ILDs are classified as a group. However, ILDs may also affect other parts of the lungs. Many ILDs have similar characteristics to IPF and most result in lung fibrosis.
There is a subgroup of ILDs called idiopathic interstitial pneumonias (IIP), where the lung tissue becomes inflamed and scarring can also occur. The word pneumonia is used to describe inflammation and not an infection such as bacterial pneumonia. IIP is further broken down into a number of pathological subtypes. These subtypes include usual interstitial pneumonia (UIP), nonspecific interstitial pneumonia (NSIP), desquamative interstitial pneumonia (DIP), respiratory bronchiolitis-associated interstitial lung disease (RB-ILD), acute interstitial pneumonia (AIP), cryptogenic organizing pneumonia (COP), and lymphocytic interstitial pneumonia (LIP). IPF is a subtype of IIP, the pathological pattern seen in IPF is UIP. It is important for your care providers to differentiate the specific subtype of interstitial disease, since treatment, management, and prognosis can vary quite dramatically.

If there is a clear association with another illness or the lung scarring (fibrosis) is the result of a side effect from a medication or an exposure to an agent known to cause PF, then the cause of the disease is no longer considered idiopathic. PF clearly associated with another disease, such as scleroderma or rheumatoid arthritis, would be referred to as pulmonary fibrosis secondary to scleroderma or secondary to rheumatoid arthritis. As we learn more about interstitial lung diseases, the terminology may evolve.

There is a subgroup of ILDs called idiopathic interstitial pneumonias (IIP), where the lung tissue becomes inflamed and scarring can also occur. The word pneumonia is used to describe inflammation and not an infection such as bacterial pneumonia. IIP is further broken down into a number of pathological subtypes. These subtypes include usual interstitial pneumonia (UIP), nonspecific interstitial pneumonia (NSIP), desquamative interstitial pneumonia (DIP), respiratory bronchiolitis-associated interstitial lung disease (RB-ILD), acute interstitial pneumonia (AIP), cryptogenic organizing pneumonia (COP), and lymphocytic interstitial pneumonia (LIP). IPF is a subtype of IIP, the pathological pattern seen in IPF is UIP. It is important for your care providers to differentiate the specific subtype of interstitial disease, since treatment, management, and prognosis can vary quite dramatically.

If there is a clear association with another illness or the lung scarring (fibrosis) is the result of a side effect from a medication or an exposure to an agent known to cause PF, then the cause of the disease is no longer considered idiopathic. PF clearly associated with another disease, such as scleroderma or rheumatoid arthritis, would be referred to as pulmonary fibrosis secondary to scleroderma or secondary to rheumatoid arthritis. As we learn more about interstitial lung diseases, the terminology may evolve.
Systemic autoimmune diseases comprise a group of immunologic disorders that can result in the development of an IIP. These disorders include connective tissue diseases (CTD) such as rheumatoid arthritis (RA), lupus erythematosus (lupus), scleroderma (systemic sclerosis; SSc), polymyositis/dermatomyositis, systemic vasculitis such as ANCA (+) polyangiitis (also called Wegener’s granulomatosis), and Churg-Strauss syndrome. The specific type of lung disease that these disorders cause is based on the underlying autoimmune disorder. The most common systemic autoimmune diseases that can result in the development of PF are SSc, RA, and lupus. Patients with CTD are also more likely to develop pulmonary hypertension (high blood pressure in the lungs). It is highly recommended that patients with CTD and symptoms of lung disease be evaluated and followed by a rheumatologist for their CTD and a pulmonologist for their lung disease.

PF can develop through significant exposure to environmental or occupational agents. Exposure to inorganic dust (asbestos, silica, beryllium, hard metal dusts), organic dust (animal proteins, bacteria, molds, fungi), or gases and fumes can contribute to the development of PF. Some of the most common forms of occupational related PF are asbestosis and silicosis. People that work in places or spend extended periods of time where there are high levels of organic dusts can develop hypersensitivity pneumonitis (HP). The two most common types of disease caused by organic dust are “bird fancier’s lung” and “farmer’s lung.” Additionally, exposure to some medications, high-dose radiation, and radiation therapy can also result in the development of PF. Medications such as antibiotics (nitrofurantoin, sulfasalazine), antiarrhythmics (amiodarone, propranolol), anticonvulsants (phenytoin), and chemotherapeutic agents (methotrexate, bleomycin, oxaliplatin) have also been associated with the development of PF.

CAUSES

PF CAN RESULT FROM A NUMBER OF CAUSES. As shown in the following figure, there are four general categories that can lead to the development of fibrotic lung disease: those of unknown or undetermined cause (teal), those that arise from a systemic autoimmune disease (gray), those that are associated with exposure to an agent known to cause PF (green), and those that have an inherited or genetic component (dark gray).

CLASSIFICATION OF COMMON INTERSTITIAL LUNG DISEASES

- Idiopathic pulmonary fibrosis (IPF)
- Acute interstitial pneumonia (AIP)
- Idiopathic non-specific interstitial pneumonia (NSIP)
- Sarcoïdosis
- Scleroderma / progressive systemic sclerosis
- Systemic Lupus erythematosus (Lupus)
- Rheumatoid arthritis
- Polymyositis / dermatomyositis
- Inorganic dust
- Organic dust
- Gases and fumes
- Radiation
- Chemotherapeutic agent
- Radiation therapy
- Antiarrhythmics
- Antibiotics
- Anticonvulsants
- Viral infections
- Bacterial infections
- Familial pulmonary fibrosis
- Hermansky-Pudlak syndrome

- Scleroderma / progressive systemic sclerosis
- Systemic Lupus erythematosus (Lupus)
- Rheumatoid arthritis
- Polymyositis / dermatomyositis
- Inorganic dust
- Organic dust
- Gases and fumes
- Radiation
- Chemotherapeutic agent
- Radiation therapy
- Antiarrhythmics
- Antibiotics
- Anticonvulsants
- Viral infections
- Bacterial infections
- Familial pulmonary fibrosis
- Hermansky-Pudlak syndrome
We know a lot about how some ILDs affect patients, but frequently a cause has not been identified. As its name suggests, the origin and development of IIPs and other idiopathic disorders, such as sarcoidosis, are still not completely understood. The most common form of IIP is IPF. The current thinking is that there is an abnormal response to injury that ultimately results in scarring of the lung. It is also hypothesized that certain environmental and genetic factors may contribute to the development of IPF; as these are more clearly defined, the disease process should be better understood. Ultimately, this should lead to new and effective treatments.

It is estimated that approximately 10–15% of patients with IPF have a form of PF that occurs in families. This is called familial pulmonary fibrosis (FPF) or familial interstitial pneumonitis (FIP). In some families with FPF/FIP, not every affected family member has the same type of IIP. In about half of families with FPF, one or more family members have IPF and another has a different form of IIP. Other forms may include NSIP, DIP, RB-ILD, and COP.

Another rare form of familial or genetic PF is Hermansky-Pudlak syndrome (HPS). There are eight different types of HPS that can be distinguished by the signs, symptoms, and underlying genetic cause; types 1, 2, and 4 are the types associated with the development of PF.

As is suggested by FPF/FIP, there is a growing body of evidence suggesting that genes or genetic variants may predispose certain individuals to developing PF or IPF.

- Studies have found that some families with a history of more than two cases of IPF carry a mutation in the surfactant protein C (SP-C) gene, which normally helps lungs function correctly.9
- Another study suggested that the presence of specific genes may predict which IPF patients will have a more severe, rapidly progressing form of the disease.10
- Shortened telomeres (telomeres protect the fragile ends of chromosomes from deterioration) may be the cause of PF in certain patients as they grow older. Mutations in the genes TERT and TERC result in shortened telomeres and appear to predispose certain individuals to PF.11,12
- Individuals with variations in the MUC5B gene, which encodes a mucus protein, may have an increased risk between 6–22 times of developing PF depending on family history.13

The clinical implications of the identification of genetic variations that are associated with PF remain unclear, as there are no therapies targeting specific genetic factors for PF. Further, there is limited availability of genetic testing to identify genes that may contribute to PF or IPF. It is therefore important for patients to discuss the potential utility and possible risks of genetic testing with a qualified genetic counselor and their health care provider.

**FACTORS ASSOCIATED WITH THE DEVELOPMENT OF PF**

- Cigarette smoking
- Prolonged exposure to occupational or environmental contaminants or dusts
- Viral or bacterial lung infections
- Certain medicines, such as some antibiotics, antiarrhythmics, anticonvulsants, chemotherapeutic agents, or therapeutic radiation
- Acid reflux disease (GERD)
- Genetic predisposition
symptoms

SYMPTOMS MAY NOT BE PRESENT early in the disease and may not occur until the disease has progressed. Most patients will have a gradual worsening of lung function over time, although some will remain stable. Some patients may experience episodes of acute worsening of lung function without a clinically apparent infection or other cause; these episodes of acute worsening are called “acute exacerbations.”

The most common symptom is shortness of breath, also known as dyspnea, which many patients describe as a feeling of breathlessness. Some patients, especially older patients, often ignore the occasional difficulty with breathing, attributing it to getting older or being out of shape. As the condition progresses and the damage to the lungs becomes more severe, breathlessness may occur with minor physical activity such as showering and getting dressed. Speaking on the phone and eating may also cause breathlessness with advanced disease.

Patients with IPF may have “clubbing” of the fingertips due to a lack of oxygen in the blood. Clubbing is a thickening of the flesh under the fingernails, causing the nails to curve downward. Clubbing of the fingertips is not specific to IPF and occurs in other lung disorders, heart and liver disease, and can also be present at birth.

Other common symptoms include:
• Chronic dry, hacking cough
• Fatigue and weakness
• Discomfort in the chest
• Loss of appetite
• Unexplained weight loss

diagnostic tests and assessments

WITHIN THE GENERAL MEDICAL COMMUNITY the lack of clinical knowledge of PF remains a concern. This is further complicated by the fact that there are more than 200 different types of ILD. Limited awareness of the causes and an inadequate understanding of disease progression have resulted in misdiagnosis of many of the ILDs. In fact, a recent study showed that more than 50% of patients with IPF might have been initially misdiagnosed.7

It was not until 1999 that the American Thoracic Society (ATS) and the European Respiratory Society (ERS), in collaboration with the American College of Chest Physicians (ACCP), described specific clinical and pathological characteristics of IPF.14 In 2011 the ATS, ERS, Japanese Respiratory Society (JRS), and the Latin American Thoracic Society (ALAT) defined evidence-based guidelines for the diagnosis and management of IPF, helping to standardize IPF diagnosis and treatment.2 In general, the diagnosis of IPF requires three factors:14

1. Exclusion of other known causes of ILD.
2. The presence of a UIP pattern on high-resolution computed tomography (HRCT) in patients not subjected to surgical lung biopsy.
3. Specific combinations of HRCT and surgical lung biopsy pattern in patients subjected to surgical lung biopsy.
Your care provider will use a series of diagnostic tests and assessments to help determine if you have PF. To determine if you have PF, and the type of PF, you may require multiple tests. Additionally, the exclusion of known causes of fibrotic lung disease requires a careful history and physical examination focusing on comorbidities, medication use, environmental exposures, and family history.

Multiple care providers from a variety of specialties, including pulmonologists, radiologists, rheumatologists, and pathologists, can help determine your diagnosis. Providers who are experienced in the diagnosis of PF can improve the accuracy of your diagnosis. To find a medical center near you with specific expertise in PF call the PFF Patient Communication Center at 844.TalkPFF (844.825.5733) or visit www.pulmonaryfibrosis.org/medicalcenters.

The tests outlined below may be used in the diagnosis of PF. If you have already been diagnosed with PF, many of these tests will be used to follow your lung health.

DIAGNOSTIC TESTS AND ASSESSMENTS

History and Physical Exam: A detailed medical history and examination to learn if there were any environmental, occupational, familial, or other medical conditions that could have contributed or predisposed a person to the disease’s development. When listening to the lungs with a stethoscope, the physician may hear “crackles” or Velcro-like sounds. These are “opening” sounds made by the small airways during inspiration.

Chest X-Ray: A routine chest X-ray may be used as a screening test. However, 5–15% of patients with significant scarring will have a normal chest X-ray and IPF cannot be diagnosed from a chest X-ray alone.

High-Resolution Computerized Tomography (HRCT): A detailed image of the lungs to help physicians more clearly identify certain radiographic patterns in the lung tissue that may indicate disease. A radiologist may identify a “honeycombing” pattern that suggests lung scarring and damage to the air sacs, or “ground-glass opacity” that refers to the hazy appearance of lung tissue that is most associated with inflammation.

Pulmonary Function Tests: Breathing tests that measure the total amount of air in the lungs and assess the flow of air in and out of the lungs. There are two important components to pulmonary function tests: (1) spirometry that measures inspired and expired lung volumes and the rate at which this occurs and (2) diffusion capacity, or DLCO, that measures the ability of oxygen to diffuse into the bloodstream. These tests are usually done in a hospital or clinical laboratory and consist of breathing into a spirometer; they are sometimes done sitting inside a large plastic enclosure that resembles a glass telephone booth.

Pulse Oximeter: A device placed on the finger or earlobe that indicates the amount of oxygen saturation in the blood. Normal ranges are 95–100% on room air. Pulse oximetry does not measure carbon dioxide levels, so a blood gas level measurement may be necessary in some patients.
Exercise Testing: A measure of how well the lungs function during exertion. Methods vary from hospital to hospital, but usually include the use of a stationary bike or treadmill. The most common method of exercise testing is the six-minute walk test, where the distance a patient can walk in six minutes is measured. Blood pressure, electrocardiogram, and oxygen saturation levels are monitored during exercise testing.

Esophogram: An X-ray examination of the esophagus (the tube that carries food to your stomach). This exam will help to determine if you suffer from GERD.

Echocardiogram (ECHO): A test that uses sound waves to create a picture of your heart, providing information about your heart function and screening for the presence of pulmonary hypertension.

Arterial Blood Gas (ABG): Direct arterial puncture to measure arterial pH, oxygen saturation (PaO2), and carbon dioxide content (PCO2). Arterial blood has been oxygenated by the lungs and thus indicates how much oxygen is available to the body.

 Bronchoscopy: Examination of the main airways of the lungs through the use of a small, flexible tube called a bronchoscope. Bronchoscopy helps to evaluate lung problems or blockages and provides a means to sample tissue or fluids. Unfortunately, the lung tissue samples obtained through bronchoscopy are small and usually inadequate for a definitive diagnosis.

 Bronchoalveolar Lavage (BAL): A way to remove a tiny sampling of cells from the lower respiratory tract using a bronchoscope. A small amount of saline is injected through the bronchoscope and, when withdrawn, removes a sample of cells from the respiratory tract. Usually this is not helpful in making the diagnosis of IPF, but may be beneficial in other clinical situations.

Surgical Lung Biopsy: Surgical lung biopsy can be an important diagnostic tool in the evaluation of patients suspected of having a fibrotic lung disorder and is generally considered the “gold standard” for diagnosis. A lung biopsy in conjunction with an HRCT can also help determine how far the disease has progressed. Usually the biopsy can be performed by a minimally invasive procedure using video assisted thoracoscopic surgery (VATS). VATS is usually well tolerated, but it may not be recommended for all individuals.
MANY PEOPLE THINK THERE ARE NO TREATMENTS FOR PF. In the past, this may have been true, but doctors do have a number of ways to treat PF, including the use of medications, oxygen therapy, non-medical treatments such as exercise, and even lung transplant surgery.

The following information is meant as a general overview on some of the treatments that physicians offer their patients with PF. This information is not medical advice. Some of these treatments may be right for some people, but no one treatment is right for everyone. Patients should speak with their doctors before starting, changing, or stopping any medical treatment. You can also learn more by contacting the PFF Patient Communication Center at 844.TalkPFF (844.825.5733) or pcc@pulmonaryfibrosis.org.

DRUG THERAPY

Azathioprine (Imuran®): Imuran® is used to suppress the immune system and is commonly used to treat autoimmune diseases such as RA. It is also used to help prevent the body from rejecting organs following transplantation. Although there have been some successful reports in a small number of individuals, the effectiveness of Imuran® to treat IPF has not been confirmed in a randomized clinical trial to date.

Corticosteroids (prednisone): Prednisone is used for suppressing the immune system and inflammation. It mimics the action of cortisol that is produced by the adrenal glands. Depending on the dose, prolonged therapy can cause the adrenal glands to stop producing cortisol. For this reason, when prednisone is discontinued, it may be necessary to gradually lower or taper the dose to allow time for the adrenal glands to recover. Since prednisone suppresses the immune system, it can potentially increase the frequency and severity of infections. Prednisone has many side effects, so individuals receiving prolonged treatment or higher doses need to be carefully monitored.

Cyclophosphamide (Cytoxan®): Cytoxan® is an anticancer drug frequently given in conjunction with prednisone or that may be given alone. While it is usually taken daily by mouth, in some instances it may also be administered intravenously.

N-acetylcysteine (NAC): NAC is a naturally occurring antioxidant. NAC was used to treat IPF in the past, but a recent study found no benefit to the use of NAC in IPF.15

Nintedanib: Nintedanib is an anti-fibrotic drug that is approved to treat IPF in the United States. In clinical trials, nintedanib has been shown to slow the decline in lung function in mild-to-moderate IPF.16 It is taken by mouth twice a day.

Pirfenidone (Esbriet®, Pirfenex®, Pirespa®): Pirfenidone is an anti-fibrotic and anti-inflammatory drug approved to treat IPF in the US, EU, Canada, and Asia. In clinical trials, pirfenidone has been shown to slow progression of mild-to-moderate IPF.17 It is taken by mouth three times a day.

OXYGEN AND PULMONARY REHABILITATION

Oxygen: Lungs exist for one reason: to move oxygen and carbon dioxide in and out of the bloodstream. Scar tissue slows down the movement of oxygen from the air sacs into the bloodstream, particularly during periods of physical activity. When oxygen levels drop in the blood, most people become breathless and begin to limit their daily activities.
If oxygen levels are low during exertion, doctors might prescribe oxygen to be worn during exertion. If oxygen levels are always low, then doctors might prescribe oxygen to be worn around the clock. Doctors might also recommend that patients monitor oxygen levels at home using a hand held pulse oximeter, which can be purchased online or in a pharmacy without a prescription.

It is often difficult to make the transition to wearing oxygen. The health benefits of wearing oxygen can be substantial: oxygen can prevent breathlessness and can help patients preserve an active lifestyle. In a different lung disease (COPD), using oxygen even helps people live longer. We encourage patients to follow their doctors’ instructions on oxygen use. Participating in a PF support group and learning more about oxygen on the PFF website can help people adjust to life with oxygen.

Pulmonary Rehabilitation: Pulmonary rehabilitation includes conditioning; exercise training and breathing exercises; anxiety, stress, and depression management; nutritional counseling; education; and other components. The goal of pulmonary rehabilitation is to restore the patient’s ability to function without extreme breathlessness. It has become the standard of care for people with chronic lung disease, and recent studies have demonstrated improvements in both exercise capacity and health-related quality of life in patients with IPF.18,19 These programs offer a variety of services and can be inpatient, outpatient, or home/community based. The programs are multidisciplinary, meaning that the team includes nurses, respiratory therapists, physical therapists, social workers, dieticians, and others.

Surgical Therapy

Lung Transplantation: PF is now the leading indication for lung transplantation in many large transplant centers. Transplantation can improve both longevity and the quality of life in properly selected patients who have no other significant health problems. Previously, it was uncommon for individuals over the age of 65 to receive transplants. However, as surgical techniques and outcomes have improved more centers are performing transplants in individuals over age 65.

Transplantation is not without risk; patients should discuss all of the potential risks and benefits of lung transplantation with their physician.

Treatment of Acute Exacerbations and Comorbidities

Patients with PF can experience periods of worsening called acute exacerbations. High-dose prednisone is usually prescribed for these episodes.2 Your doctor may provide prednisone or other treatments if you have an acute exacerbation.

Patients with PF frequently have other associated conditions, called comorbidities, as well. These can include pulmonary hypertension, GERD, obesity, emphysema, and obstructive sleep apnea. Your treatment plan will likely include both treatments that are directed at your PF and treatments for your comorbidities. Your care providers will help you determine how your comorbidities should be treated.
CLINICAL TRIALS

Many patients choose to participate in clinical trials after consulting with their physician. A clinical trial is a study performed to determine if an experimental treatment is safe and/or effective to treat a specific medical condition.

The research community is aggressively investigating new treatments for all forms of PF. While the long-term goal of research is to prevent and cure the disease, present therapeutic approaches consist of attempts to slow disease progression and to extend the life expectancy of PF patients. While some studies are in advanced stages of development, others are in much earlier stages. There are a variety of clinical trials that are actively seeking the participation of patients.

Please contact the PFF Patient Communication Center at 844.TalkPFF (844.825.5733) or pcc@pulmonaryfibrosis.org to learn more about clinical trials. More information is also available on the PFF website at www.pulmonaryfibrosis.org/life-with-pf/clinical-trials.

CONTINUED MONITORING OF YOUR PF is a very important part of maintaining your health. Through monitoring, you and your care providers can determine how well you are responding to your treatment, whether your disease is stable, and what next steps should be taken. Regular interactions with your care providers will also help ensure that you receive the most current and best possible PF treatments.

Your clinical monitoring pattern will vary dependent upon your specific type of PF. Regardless of the underlying cause of your PF, continued monitoring is a vital component in your treatment. Talk with your provider about how frequently you should see them and what steps need to be taken to ensure that your disease is properly managed.
palliative and hospice care

THE MAIN GOAL OF BOTH PALLIATIVE AND HOSPICE CARE IS MAINTAINING PATIENT COMFORT. Palliative care does not specifically treat PF, but is care designed to improve the quality of life for patients with a chronic illness. Accordingly, it is appropriate for any patient who experiences discomfort due to PF.

PALLIATIVE CARE

Using a multidisciplinary approach, palliative care can involve physical, psychosocial, and spiritual factors in the treatment approach. Teams may include physicians, pharmacists, nurses, religious leaders, social workers, psychologists, and other health care professionals. In patients with PF, these teams focus on concrete goals including relief from pain or other distressing symptoms, spiritual care, development of support systems, and encouraging an active lifestyle.

HOSPICE CARE

Hospice care is a type of end-of-life care; it is intended to help people who are dying have peace, comfort, and dignity. It is generally reserved for patients who have less than six months to live. Patients in hospice care receive treatments to control pain and other symptoms to maintain comfort. Hospice care also provides support to families. Care may be provided at a hospice center, but can also be done in nursing facilities, hospitals, or at home.

lifestyle changes

THERE ARE A VARIETY OF THINGS that patients can do to maintain or improve their quality of life while living with PF. The National Institutes of Health (www.nih.gov) and the Mayo Clinic (www.mayoclinic.org) offer a variety of recommendations for patients, some of which we have referenced in this section.

Stay in Shape. The most damaging consequence of lung disease and its sensation of breathlessness is the development of an inactive lifestyle. For many patients, activities of daily living, like bathing and dressing, can create overwhelming fatigue. “Air hunger” can create panic attacks, and produce negative psychological effects. People with chronic respiratory problems sometimes limit their physical activities in an attempt to avoid shortness of breath. The lack of exercise works against you; inactivity weakens your muscles and they become less efficient. Deconditioning can make even the simplest daily activities more difficult. Regular exercise strengthens your muscles and makes them more resistant to fatigue. With practice and training you can learn to perform tasks in a more efficient manner. By being more efficient you need less oxygen for the same amount of work. The result is that you may find that you have more energy to accomplish daily tasks and that you are less short of breath. A formal rehabilitation program (pulmonary rehabilitation) is preferred because it allows for observation during exercise and it can be tailored to your specific needs.

Eat Well. A healthy diet includes a variety of fruits, vegetables, and whole grains. It also includes lean meats, poultry, fish, beans, and fat-free or low-fat dairy products. A healthy diet is low in saturated fat, trans fat, cholesterol, sodium (salt), and added sugar. Eating smaller, more frequent meals may
prevent stomach fullness that can make it harder to breathe. If you need help with your diet, ask your doctor to arrange for a dietician to work with you. A nutritionally rich diet that contains adequate calories is essential. A dietician can give you further guidelines for healthy eating.

Get Plenty of Rest. Getting at least eight hours of quality rest every night can boost your immune system and sense of well-being.

Stop Tobacco Use. Avoiding environmental irritants, like cigarette smoke, is a good way to prevent further damage to your lungs. If you are still smoking, the most important thing you can do is to stop. Due to the addictive nature of tobacco, this can be difficult. Seek the help of your physician to find a smoking cessation class or other beneficial methods to help you stop smoking. Secondhand smoke can be as harmful to you as if you were smoking yourself. Ask your family and friends to refrain from smoking around you.

Learn and Practice Relaxation Techniques. When you are physically and emotionally relaxed, you avoid excessive oxygen consumption caused by tension of overworked muscles. Additionally, learning relaxation techniques can help you manage the panic that often accompanies shortness of breath. Joining a support group and/or seeing a counselor can help you cope with your feelings and the anxiety and depression that are common in people with chronic breathing disorders; these feelings may aggravate the underlying disease. Many fear losing the ability to function and becoming dependent on others. The restriction on activity due to shortness of breath may lead to isolating oneself from family and friends, adding to the depression.

Join a Support Group. Just knowing that there is someone out there that knows how you feel is comforting. Share ideas, share fears, and share joys. A detailed listing of local and online support groups can be found at www.pulmonaryfibrosis.org/supportgroups.

Participate in Your Health Care. Remember you are part of a health care team that includes your doctors and nurses. They will be asking you a lot of questions. As a member of that team you have a responsibility to do your part. Be prepared to ask your own questions. Be a participant. Bring someone with you to each appointment and prepare a list of questions to be answered by your physician during your visit.

Help Others with PF. Consider participating in the Pulmonary Fibrosis Foundation’s advocacy program. You may gain strength in knowing that you are helping future patients and researchers by advocating for the pulmonary fibrosis community.

Keep a Positive Attitude. Actively participating in the management of your disease is greatly enhanced by a positive attitude. A positive attitude can help you and your loved ones cope with your disease.
maintaining your care

YOU ARE THE CENTER OF YOUR TREATMENT. While your doctors, nurses, and other care providers will help you manage your disease, you are your most important advocate. People who take an active role in their own care do better over time. Here are a few steps you can take to make sure you maximize your care:

Speak up for yourself. If you have any concerns with your treatment or do not understand something about your disease, talk to your care providers. They want to make sure that you are able to maintain your health and will help you with these issues.

Be prepared for your visits. Ensure that you are able to see your care providers regularly. Bring a list of any questions or concerns.

Ask questions of your care providers. This goes along in communicating with your providers and being prepared. You cannot help in the decision making process if you do not understand the factors involved.

Take notes. You will likely get a lot of information during your health care visits and this can be overwhelming. Do not be afraid to take notes to help you remember important treatment issues later on.

Let your family and friends help. Emotional support is as important as other treatments. You can bring people who support you to your health appointments. Additionally, maintaining your health is a lot easier if you have support. This is especially true if you are trying to modify your lifestyle. Quitting smoking, exercising more, or changing your diet is difficult; let those who care about you help you accomplish your goals.

Contact advocacy and support groups. Reach out to community or national groups that help people with PF. It can be very useful to find out how other people manage their disease. They may give you invaluable tips or tools that make it easier for you to manage your disease. You can also pass your tips on to others and help support the community.

Stay informed. Keep learning about PF. The more you know, the better you will be able to manage your disease and recognize when you need to access health services. Be warned that there is misinformation on the internet; make sure you access reliable sources of information, such as advocacy groups and respected scientific and medical sources.

YOUR CARE TEAM

- Pulmonologist / Primary care provider
- Other team members / Consultants
- Nurses / Physician assistants
- Community partners / Support
questions to ask your health care providers

YOUR CARE PROVIDERS ARE PARTNERS in your PF treatment. It is important that you have a firm understanding of your disease and how you should care for it. Ask your providers about anything relating to your treatment that you do not fully understand. Here are a few questions that may help you manage your care:

How will PF impact what I can and cannot do?
You probably already know the limits of what you can and cannot do in your everyday routine. There may be activities that you do not regularly engage in which may be impacted by your PF. This can include traveling by air or visiting high-altitude places. Your care providers can help you identify what activities may present some challenges.

What should I do and whom should I contact if I have any problems with my PF?
Having an action plan in place in case of problems is a must for anyone with a chronic disease. Ask about where you should go, who you should call, and what you should do during nights and weekends if you have a problem with your PF. You should also know who to contact if you have any questions and concerns about your current care, including your treatment.

When is the right time to start or switch treatment?
The decision to start therapy depends on your health and desires. It should be made in conjunction with your health care providers and those who will help support you, such as family and friends. Once you have started therapy, you may need to change it as your disease and needs evolve. Of course, when your treatment is not working well it is time to discuss other treatment options. However, even when treatment is working there may be better options for your needs.

Asking about what options are available is a good way to find out what changes are happening in the treatment of PF and helps make sure that you get the best treatment for both your disease and lifestyle.

Will my treatment interfere with other medications I am taking?
It is very important that your care providers know all of the medications that you take regularly—both prescribed and over-the-counter—as well as any vitamins or other nutritional supplements. Asking your providers about drug-drug interactions helps ensure that all of your medications are reviewed for potentially dangerous interactions.

Are there resources that can help me lead a healthier lifestyle?
Improving your lifestyle is a critical component of improving quality of life. However, changing things like how much you exercise, your diet, and smoking habits can be very difficult. Care providers may be able to direct you to resources that can help you modify your lifestyle and adopt healthier behaviors. These can include support groups, dieticians, and personal trainers. Showing an interest in adopting healthier behaviors is the first step in accomplishing these changes.

Is a clinical trial right for me?
Clinical trials are a potential resource for patients who may not have many good treatment options. However, whether you should enroll in a clinical trial depends on many factors, including what trials are available in your area, whether you are motivated to participate, and your current condition. If you are interested in participating in a clinical trial, talk with your care providers about options; they will help you determine if a clinical trial is right for you.
about the pulmonary fibrosis foundation

THE MISSION OF THE PULMONARY FIBROSIS FOUNDATION (PFF) is to serve as the trusted resource for the pulmonary fibrosis (PF) community by raising awareness, providing disease education, and funding research.

By actively engaging the PF community, the Pulmonary Fibrosis Foundation has developed essential programs available to those living and working with pulmonary fibrosis. Our signature programs include:

- PFF Care Center Network
- PFF Patient Registry
- PFF Patient Communication Center
- PFF Ambassador Program
- An international network of support groups and online communities
- The PFF Summit
- Comprehensive disease education materials

Our physician staff, expert Medical Advisory Board, and the biennial PFF Summit allow us to maintain an ongoing dialogue with physicians, researchers, industry representatives, and the patient community. This creates a collaborative environment that will help us achieve many of our goals.

Our peer-reviewed research program supports projects that improve understanding of pulmonary fibrosis and will lead to successful therapies. We have developed significant relationships with industry partners and upheld our position as the honest broker to inform those affected by pulmonary fibrosis of important scientific breakthroughs.

PULMONARY FIBROSIS FOUNDATION
230 East Ohio Street, Suite 304  phone 844.TalkPFF (844.825.5733)
Chicago, Illinois 60611-3201  email pcc@pulmonaryfibrosis.org

STAY CONNECTED WITH THE PFF
Your engagement helps the PF community promote disease education, strengthen support groups, and grow innovative research efforts as we strive to cure this devastating disease.

Contact the PFF and request to receive:
- Invitations to PFF Disease Education Awareness events including monthly webinars
- Information about online communities and support groups
- The PFF monthly e-newsletter
- The PFF biannual Breathe Bulletin
- Email updates regarding
  - Clinical trial updates
  - Emerging therapies
  - Support group announcements
  - Team PFF announcements and invitations
  - Call to action and fundraising announcements

DONATE TO THE PFF AS AN INVESTMENT TO HELP FIND A CURE
Ways to Give:
- Make a gift of cash
- Create an online tribute
- Donate stocks and bonds
- Establish a charitable gift annuity for the benefit of the PFF
- Celebrate lifetime events

Call 844.TalkPFF (844.825.5733) or visit www.pulmonaryfibrosis.org to make a gift or request to be added to our mailing list.
glossary

**Acute exacerbation**: An episode of rapid decline or the emergence of symptoms.

**Alveoli**: Tiny air sacs in the lungs where carbon dioxide leaves the bloodstream and oxygen enters the bloodstream.

**Bronchoscope**: A tool used for inspecting the inside of the lungs.

**Comorbidity**: A disease or other issue that occurs simultaneously with PF.

**Diffuse parenchymal lung diseases (DPLD)**: Another name for interstitial lung diseases.

**Diffusion capacity (DLCO)**: A measure of the ability of oxygen to diffuse into the bloodstream.

**Dyspnea**: Difficulty breathing or shortness of breath.

**Fibroproliferation**: Of or relating to the growth of fibroblasts, one of the basic connective tissue cells.

**Fibrosis**: An increase in fibrous scar tissue.

**Forced expiratory volume (FEV1)**: The amount of air you can blow out in one second. Measured by spirometry.

**Forced vital capacity (FVC)**: How much air you can blow out of your lungs. Measured by spirometry.

**Gastroesophageal reflux disease (GERD)**: A regurgitation of stomach acids into the esophagus and throat, causing heartburn, acid indigestion, and possibly injury to the lining of the esophagus. Also called acid reflux disease.

**Hospice care**: Palliative care for patients at end-of-life.

**Idiopathic**: Of unknown cause.

**Idiopathic interstitial pneumonias (IIP)**: A type of interstitial lung disease. IPF is a type of IIP.

**Interstitial lung diseases (ILD)**: A broad category of over 200 lung diseases that affect the lung interstitium.

**Interstitium**: The walls of the air sacs of the lung. If you hold a lung in your hand, you would be holding the interstitium.

**Palliative care**: Non-curative therapy that treats symptoms and focuses on improving quality of life. It can be received at the same time as curative therapy.

**Pathologist**: A physician specializing in disease-associated changes in tissue and organs. Pathologists aid in medical diagnosis.

**Pulmonary**: Relating to the lungs.

**Pulmonary hypertension**: Abnormal high blood pressure in the lung arteries.

**Pulmonologist**: A physician specializing in the lungs.

**Radiologist**: A physician specializing in using radiology tests (e.g., X-rays) to diagnose illness.

**Rheumatologist**: A physician specializing in rheumatic diseases, which may include autoimmune diseases and joint diseases.

**Spirometry**: A test that measures the amount of air inhaled and exhaled with each breath.

**Usual interstitial pneumonia (UIP)**: A specific abnormal radiologic or pathologic pattern.
